Institute for Quantitative Social Science
Harvard University

Thanks, in Mexico, to Edith Arano, Carlos Avila, Juan Eugenio Hernández Avila, Mauricio Hernández Avila, Jorge Carreon Manuel Castro, Octavio Gómez Dantes, Sara Odette León, Héctor Hernández Llamas, René Santos Luna, Tania Martínez, Gustavo Olaíz, Maritza Ordaz, Eduardo González Pier, Héctor Peña, Raymundo Pérez, Esteban Puentes, Corina Santangelo, Sergio Sesma, Sara Uriega, Martha María (Mara) Tellez; at Harvard, to Dennis Feehan, Emmanuela Gakidou, Jason Lakin, Diana Lee, Ryan T. Moore, Nirmala Ravishankar, Manett Vargas, and our Panel of Experts, Edmundo Berumen, Luis Felipe Lopez Calva, Nora Claudia Lustig, Thomas Mroz, John Roberto Scott.
The First Results of our Evaluation
(Effect of Random Assignment on One Mexican)

Before Treatment

After Treatment

(Manett’s) Arturo Vargas
Evaluation Components

- Impact Evaluation (today’s talk)
- National Level Analysis
- Process Evaluation
- In-depth Focus Groups
Goals of SP & Evaluation Outcome Measures

- **Financial Protection**
  - Out-of-pocket expenditure
  - Catastrophic expenditure (now 3% of households spend > 30% of disposable income on health)
  - Impoverishment due to health care payments

- **Health System Effective Coverage**
  - Percent of population receiving appropriate treatment by disease
  - Responsiveness of Seguro Popular
  - Satisfaction of affiliates with Seguro Popular

- **Health Care Facilities**
  - Operations, office visits, emergencies, personnel, infrastructure and equipment, drug inventory.

- **Health**
  - Health status
  - All-cause mortality
  - Cause-specific mortality
Data Sources

- Panel survey \((n = 36,000)\) at time 0 and 10 months later
- Aggregate data describing health clinics and areas around them
- Health facilities survey
- Focus group interviews
Quantities of Interest, for Each Outcome Variable

- Effect of rolling out the policy in an area ("intention to treat")
  - Affiliating the poor automatically
  - Establishing an MAO, so people can affiliate
  - Encouraging others to affiliate: painting buildings, radio, TV, loudspeakers, etc.

- Effect of one Mexican affiliating with SP ("treatment effect")

- Compliance rates:
  - Difference between intention to treat and treatment
  - A measure of program success

- Variation in effect size
  - Areas with no health facilities: SP effect zero
  - People who already have access to health care: SP effect small
  - Places with better doctors and health administration: bigger effects
Ideal Design for Mexican Society

- Roll out SP as fast as possible to as many as possible
  - Unless SP doesn’t work!
  - Unless we can improve outcomes by learning from sequential affiliation
- Immediately give all Mexicans equal ability to affiliate
  - **Impossible**: insufficient health facilities in some areas
  - **Politically Infeasible**: local officials want benefits for their favored areas first
How “Ideal Designs” Make Evaluation Hard

- If anyone can affiliate
  - The older and sicker will affiliate first
  - Younger and healthier will affiliate less
  - I.e., affiliates are sicker than non-affiliates
  - Evaluation: affiliating makes you sick!
  - This is the problem of “selection bias”

- If politicians (in a democracy) decide which areas get MAOs
  - Privileged areas get affiliation first
  - Political favorites are affiliated early
  - Even if SP has no effect, areas with SP will be healthier
A Feasible Design for Scientific Evaluation
First Define and Choose Health Clusters

- Divide country into “health clusters”
  - Clínicas, centros de salud, hospitales, etc., and catchment area
  - Catchment area based on time to service
  - Rural clusters: set of localidades that use the health unit.
  - Urban clusters: set of AGEB’s that use the health unit.

- Reasons to exclude areas from evaluation
  - Political: politicians want favorite areas covered; some don’t want their states participating in the evaluation
  - Institutional: Drop (rural) clusters without adequate facilities
  - Administrative: Drop (rural) clusters with < 1000 population; Only include urban clusters with 2,500–15,000 population
  - Methodological: Drop areas where affiliation had already started
Remaining in study: 148 clusters in 7 states

- Sonora
- Jalisco
- Guerrero
- Oaxaca
- Morelos
- San Luis Potosi
- Estado de México
States and Clusters not Selected Randomly

- **Effect of SP on the areas studied**
  - estimated well (using methods to be described)

- **Ways to Estimate Effects of SP on all of Mexico**
  - Assume constant effects: probably wrong
  - Hints from present study: how effects of SP varies due to geography, income, age, sex, etc.
  - Extrapolation: entirely model dependent
  - **Our strategy: Repeat design in other areas**
  - Same strategy as in most medical intervention studies
Who Can Affiliate?

Constraints

- Must choose clusters to roll out program, and
  - Affiliate the poor automatically
  - Establish an MAO, so people can affiliate
  - Encourage people to affiliate: radio, TV, loudspeakers, knock on doors, paint buildings, etc.
- Financial constraints: rollout must be staged over time

Randomized Evaluation Design

- Randomly select half of the 148 clusters for encouragement
- Other clusters to get encouragement at a later date
- Any Mexican family may still affiliate at any time
- No randomization at individual level
- Without an evaluation, choices would still be made, but would be arbitrary choices made by local government officials
Goal: equivalent treatment and control groups
Classical random assignment achieves equivalence:
- on average (or with a large enough $n$), and
- if nothing goes wrong
But, if we lose clusters
- Equivalence of affiliate and non-affiliate clusters could fail
- E.g., maybe poor, unhealthy clusters are more likely to drop out
Consequence: Bias in evaluation conclusions
We need estimators robust not merely to statistical assumptions but to real world problems
We Use: Paired Matching, then Randomization

**Design**
- Sort 148 health clusters into **74 matched pairs**
- Choose clusters within each pair to be as similar as possible
- Randomly choose one cluster in each pair for encouragement

**Advantages**
- Matching controls for **observable confounders**, to a degree
- Randomization controls for observable and **unobservable confounders**, to a degree
- Pairing provides failure safeguard: drop entire pair, and treatment and control groups remain equivalent
- One such failure has already occurred
More Detail on Matching Procedure

- Select background characteristics
  - Ideally: outcome measures at time 1 (based on a survey done before random assignment)
  - Next best: proxies highly correlated with the outcome measures
  - Practically: All available, plausibly relevant variables (38 covariates for both Rural & Urban; 30 in common)
    - demographic profiles
    - socioeconomic status
    - health facility infrastructure
    - geography and population

- Exact match on state and urban/rural

- Compute “distance” between every possible pair of clusters (using Mahalanobis Distance, normalized with all state-validated clusters)

- An “optimally greedy” matching algorithm:
  - Select matched pair with smallest distance between clusters
  - Repeat until all clusters are used
Experimental Design Implementation

- At the last moment: Flip coin to choose treatment and control cluster for each pair
- Treatment assignments delivered to state governments
- Intensive affiliation begins in treatment clusters
- 74 matched treatment-control pairs in the evaluation: 55 rural and 19 urban in 7 states

Gary King (Harvard)  Evaluation of Seguro Popular: Baseline Analy
### Design has three parts

1. Matching pairs on observed covariates
2. Randomization of treatment within pairs
3. Parametric analysis adjusts for remaining covariate differences

### Triple Robustness

If matching or randomization or parametric analysis is right, but the other two are wrong, results are still unbiased

### Two Additional Checks if Triple Robustness Fails

1. If one of the three works, then “effect of SP” on time 0 outcomes (measured in baseline survey) must be zero
2. If we lose pairs, we check for selection bias by rerunning this check

Household Survey Design

- Baseline in August 2005; followup mid-2006.
- Questionnaire jointly written; implemented by National Institute of Public Health of Mexico (INSP)

**Contents**

- Questions on: expenditure, insurance, Seguro Popular, sociodemographic characteristics, health status, effective coverage, health system responsiveness and utilization, outpatient and inpatient care, social capital, and stress.
- Physical tests: blood pressure, cholesterol, blood sugar and HbA1c.

We have 74 matched pairs, but can only (feasibly) survey 50; Sample size: 36,000 households (up to 380 per cluster)

**How to choose?**

- Minimize potential for omitted variable bias by choosing pairs with smallest Mahalanobis Distance
- Reduce non-compliance problems by including highest percentage of population in incomes in deciles I and II (automatically affiliated)

**Result:** 45 rural and 5 urban pairs

**Remaining 24 pairs:** also used with aggregate outcomes

Health Facilities Survey

- Sample size: 148 health units (corresponding to the pairs of health clusters in the study).
- Panel design
  - first measurement (baseline) in October 2005.
  - follow-up measurement in July-2006.
- Design and implementation:
  - Survey questionnaire designed by Harvard Team
  - Implementation by INSP
- Contents
  - Information on health unit operation, office visits, emergencies, personnel, infrastructure and equipment, and drug inventory.
  - Information on admissions and discharges.
